# Exam \#3 STA-209 Sections 03, 05 

Name: $\qquad$

## Directions

- Several questions have a suggested number of sentences for your answer. This is to help indicate the scope of solution I am looking for (i.e., you do not always need every single detail) and to discourage you from "information dumping"
- Information that is included with your answer that is not relevant to the problem will not help you but will still be graded for correctness. In other words, including more information than is asked for can generally only hurt you
- You do not need to write in complete sentences: bullet points are completely acceptable and even preferred

## Question 1

Below I will describe a number of different study designs. You will be asked to
(1) Identify the null hypothesis
(2) Identify the correct statistical test for this hypothesis

Part A: For this study, I am interested in determining if a student's major (Humanities/STEM/Social Sciences) is associated with their final exam score in STA-209.

Major: categorical variable
Score: continuous
Null H0: no association/no difference in mean exam score
Test: ANOVA or t-test with Bonferonni correction

Part B: A two-day workshop for learning basic R has been created, where attendees are tested in their R skills both prior to the workshop and after the workshop has been completed. For each of these tests, a numeric score is given. We wish to determine whether or not the workshop has been effective in improving the R skill of the attendees.

Score: continuous
Category: before and after
H0: No difference before and after session
Test: paired t-test

Part C: Binge drinking is defined as a pattern of drinking that involves consuming 5 or more standard drinks within 2 hours. Respondents of a survey were asked for their sex and whether or not they have engaged in binge drinking more than twice in the previous week. We wish to determine whether or not there is a difference in binge drinking patterns between men and women.

Sex: Categorical
Binge Drinking (yes/no): Categorical (2 categories)
Test: Difference in proportion
H0: No difference between men and women
or
Test: $\chi^{2}$ test of independence
H0: no association between sex and binge drinking

## Question 2

Cocaine addicts have been reported to have a significant depletion of stimulating neurotransmitters and thus continue to use cocaine to avoid feelings of depression and anxiety. A 3 -year study with 72 chronic cocaine users compared an antidepressant drug called desipramine with lithium and a placebo (lithium is the standard treatment for cocaine addiction). One third of the subjects were randomly assigned to each treatment group with the following results:

|  | Relapse | No Relapse |
| :--- | ---: | ---: |
| Desipramine | 10 | 14 |
| Lithium | 18 | 6 |
| Placebo | 20 | 4 |

Part A: What type of plot would you use to visually display these results

Stacked or conditional bar chart (treatment on x axis, number on y axis, color for relapse)

Part B: Describe the null hypothesis of this study and construct a table of expected counts under the assumption of the null hypothesis.
$\chi^{2}$ test of independence, null is that there is no association between treatment and outcome

```
m <- matrix(c(10,14,18,6,20,4), nrow = 3, byrow = TRUE)
rownames(m) <- c("Desipramine", "Lithium", "Placebo")
colnames(m) <- c("Relapse", "No Relapse")
m %>% addmargins()
\begin{tabular}{lrrr} 
\#\# & Relapse & No Relapse & Sum \\
\#\# Desipramine & 10 & 14 & 24 \\
\#\# Lithium & 18 & 6 & 24 \\
\#\# Placebo & 20 & 4 & 24 \\
\#\# Sum & 48 & 24 & 72
\end{tabular}
# Under the null
# expectred count of desipramine and relpase is product of probabilities
(24/72)*(48/72) * 72
## [1] 16
(24*48)/72
## [1] 16
cc <- chisq.test(m)
## Observed counts
m
## Relapse No Relapse
## Desipramine 10 14
## Lithium 18 6
## Placebo 20 4
# expected counts
cc$expected
\begin{tabular}{lrr} 
\#\# & Relapse & No Relapse \\
\#\# Desipramine & 16 & 8 \\
\#\# Lithium & 16 & 8 \\
\#\# Placebo & 16 & 8
\end{tabular}
```

Part C: The $\chi^{2}$ test statistic has a value of $\chi^{2}=10.5$ with a p-value of $p$-val $=0.0052$. Based on this, what conclusion would you reach if testing at the $\alpha=0.05$ level?

We would reject since $p<\alpha=0.05$

## Question 3

## Model 1:

lm(formula $=$ Net_Tuition $\sim$ Enrollment, data $=$ college)
Coefficients:
Estimate Std. Error $t$ value $\operatorname{Pr}(>|t|)$
(Intercept) $14225.3137 \quad 272.8034 \quad 52.1<0.000000000000002$ *** $^{*}$

| Enrollment | -0.0820 | 0.0265 | -3.1 | 0.002 ** |
| :--- | :--- | :--- | :--- | :--- |

Residual standard error: 7180 on 1093 degrees of freedom
Multiple R-squared: 0.00869, Adjusted R-squared: 0.00779
F-statistic: 9.58 on 1 and 1093 DF, p-value: 0.00201

## Model 2:

lm(formula $=$ Net_Tuition $\sim$ Enrollment + Type, data $=$ college $)$
Coefficients:
Estimate Std. Error t value $\operatorname{Pr}(>|\mathrm{t}|)$
(Intercept) $5746.1019 \quad 377.2481 \quad 15.2<0.0000000000000002$ ***
Enrollment $0.2533 \quad 0.0239 \quad 10.6<0.0000000000000002$ ***
TypePrivate $10808.5970 \quad 398.6370 \quad 27.1<0.0000000000000002$ ***
Residual standard error: 5550 on 1092 degrees of freedom
Multiple R-squared: 0.408, Adjusted R-squared: 0.406
F-statistic: 376 on 2 and 1092 DF, p-value: <0.0000000000000002

Part A: For this part, consider Model 1 from above. What is the null hypothesis in linear regression? Based on the summary output, how would you describe the relationship between enrollment and tuition?

H0: no linear relationship between enrollment and net tuition
Summary: Based on summary, evidence to suggest that there is a linear relationship so we reject H0
Describe: seems that negative linear relationship

Part B: Now consider Model 2, which includes an indicator for whether or not a college is private. How would you interpret the intercept in this model? Is this a meaningful value in this model?

Intercept: reference var is public school
Interpretation: 5746 is estimated tuition for public school when enrollment $=0$
Meaningful?: No.

Part C: Compare the coefficient for Enrollment between Model 1 and Model 2. What has changed? In other words, what impact has adding an indicator for Private had on this value, and why did it result in such a drastic change?

Big change: from negative to positive
Why: because now considering within public/private groups
Name for phenomena (not on test): Simpson's Paradox
